
CLOUD COMPUTING

CLOUD COMPUTING:

CLOUD COMPUTING IS THE DELIVERY OF COMPUTING SERVICES—including servers, storage, databases, networking, software, analytics, and intelligence—OVER THE INTERNET (“THE CLOUD”) TO OFFER FASTER INNOVATION, FLEXIBLE RESOURCES, AND ECONOMIES OF SCALE. YOU TYPICALLY PAY ONLY FOR CLOUD SERVICES YOU USE, HELPING LOWER YOUR OPERATING COSTS, RUN YOUR INFRASTRUCTURE MORE EFFICIENTLY AND SCALE AS YOUR BUSINESS NEEDS CHANGE.

Benefits of cloud computing:

■ Cost

Cloud computing eliminates the capital expense of buying hardware and software and setting up and running on-site datacenters—the racks of servers, the round-the-clock electricity for power and cooling, the IT experts for managing the infrastructure. It adds up fast.

■ Speed

Most cloud computing services are provided self service and on demand, so even vast amounts of computing resources can be provisioned in minutes, typically with just a few mouse clicks, giving businesses a lot of flexibility and taking the pressure off capacity planning.

■ Global scale

The benefits of cloud computing services include the ability to scale elastically. In cloud speak, that means delivering the right amount of IT resources—for example, more or less computing power, storage, bandwidth—right when it is needed and from the right geographic location.

- **Productivity:**

On-site datacenters typically require a lot of “racking and stacking”—hardware setup, software patching, and other time-consuming IT management chores. Cloud computing removes the need for many of these tasks, so IT teams can spend time on achieving more important business goals.

- **Performance**

The biggest cloud computing services run on a worldwide network of secure datacenters, which are regularly upgraded to the latest generation of fast and efficient computing hardware. This offers several benefits over a single corporate datacenter, including reduced network latency for applications and greater economies of scale.

- **Reliability**

Cloud computing makes data backup, disaster recovery and business continuity easier and less expensive because data can be mirrored at multiple redundant sites on the cloud provider's network.

- **Security**

Many cloud providers offer a broad set of policies, technologies and controls that strengthen your security posture overall, helping protect your data, apps and infrastructure from potential threats.

		Traditional Computing	Cloud Computing	
	1	Data storage on local Internal / hard drive	Data storage in the cloud or external server	
	2	Extra storage – pay for hardware, no unlimited storage	Unlimited storage – no extra hardware required	
	3	For hardware configuration, you may hire expert	No need to do hardware configuration – dynamic resources	
	4	Pay for power, electricity, AC cooling etc.	No expense on power, electricity, AC cooling etc.	
	5	If you need to add new server it will take few days and more charges apply.	Pay for use, dynamic resources allocation.	
	6	Fixed charges – installation, hardware used.	If resources are use less, then pay less	
	7	Lack of isolation – high risk of security and poor performance.	No need to worry about security / loss of data.	
	8	Backup and recovery take risky.	Backup and recovery very easy.	
	9	Extra pay for software installation & upgrade.	Automatic software upgrade available	
	10	Pay for extra hardware & other resources	On demand resources	

- **Cloud Computing architecture:**

Cloud Computing architecture comprises of many cloud components, which are loosely coupled. We can broadly divide the cloud architecture into two parts:

- **Front End**

- **Back End**

Each of the ends is connected through a network, usually Internet.

- **Front End**

The **front end** refers to the client part of cloud computing system. It consists of interfaces and applications that are required to access the cloud computing platforms, Example - Web Browser.

- **Back End**

The **back End** refers to the cloud itself. It consists of all the resources required to provide cloud computing services. It comprises of huge data storage, virtual machines, security mechanism, services, deployment models, servers, etc.

- **Cloud infrastructure** consists of servers, storage devices, network, cloud management software, deployment software, and platform virtualization.

- **Hypervisor:**

Hypervisor is a **firmware** or **low-level program** that acts as a Virtual Machine Manager. It allows to share the single physical instance of cloud resources between several tenants.

- **Management Software:**

It helps to maintain and configure the infrastructure.

- **Deployment Software:**

It helps to deploy and integrate the application on the cloud.

- **Network:**

It is the key component of cloud infrastructure. It allows to connect cloud services over the Internet. It is also possible to deliver network as a utility over the Internet, which means, the customer can customize the network route and protocol.

- **Server:**

The **server** helps to compute the resource sharing and offers other services such as resource allocation and de-allocation, monitoring the resources, providing security etc.

- **Storage:**

Cloud keeps multiple replicas of storage. If one of the storage resources fails, then it can be extracted from another one, which makes cloud computing more reliable.

- **Infrastructural Constraints:**

Fundamental constraints that cloud infrastructure should implement are shown in the following diagram:

- **Cluster Computing:**

Cluster computing or *High-Performance computing* frameworks is a form of computing in which bunch of computers (often called nodes) that are connected through a LAN (local area network) so that, they behave like a single machine. A computer cluster help to solve complex operations more efficiently with much faster processing speed, better data integrity than a single computer and they only used for mission-critical applications.

Some of the critical Applications of Cluster Computers are Google Search Engine, Petroleum Reservoir Simulation, Earthquake Simulation, Weather Forecasting.

- **Types of Cluster computing:**

- 1. **Load-balancing clusters:** As the name implies, This system is used to distribute workload across multiple computers. That system distributes the processing load as possible across a cluster of computers.
- 2. **High availability (HA) clusters:** A high availability clusters (HA cluster) are the bunch of computers that can reliably utilise for redundant operations in the event of nodes failure in Cluster computing.
- 3. **High performance (HP) clusters:** This computer networking methodology use supercomputers and Cluster computing to solve advanced computation problems.

Advantages of using Cluster computing

1. **Cost efficiency:** In a Cluster computing Cost efficiency is the ratio of cost to output, that is the connecting group of the computer as computer cluster much cheaper as compared to mainframe computers.
2. **Processing speed:** The Processing speed of computer cluster is the same as a mainframe computer.
3. **Expandability:** The best benefit of Cluster Computing is that it can be expanded easily by adding the additional desktop workstation to the system.
4. **High availability of resources:** If any node fails in a computer cluster, another node within the cluster continue to provide uninterrupted processing. When a mainframe system fails, the entire system fails.

- **Grid Computing:**

Grid computing is the practice of leveraging multiple computers, often geographically distributed but connected by networks, to work together to accomplish joint tasks. It is typically run on a “data grid” a set of computers that directly interact with each other to coordinate jobs.

- **How Does Grid Computing Work?**

Grid computing works by running specialized software on every computer that participates in the data grid. The software acts as the manager of the entire system and coordinates various tasks across the grid. Specifically, the software assigns subtasks to each computer so they can work simultaneously on their respective subtasks. After the completion of subtasks, the outputs are gathered and aggregated to complete a larger-scale task. The software lets each computer communicate over the network with the other computers so they can share information on what portion of the subtasks each computer is running, and how to consolidate and deliver outputs.

How Grid Computing Works

©2008 HowStuffWorks

In a basic grid computing system, every computer can access the resources of every other computer belonging to the network.

Grid computing is distinguished from the cluster computing, because in Grid computing each node has heterogeneous and geographical dispersed (such as WAN) and its own resource manager and perform a different task, but in cluster computing resources are managed in a single location. Grid computing is a way of using resources optimally inside an organization.

- **TYPES OF GRID:-**

There are many types of grid like:-

- 1) **COMPUTATIONAL GRID:-** It acts as the resource of many computers in a network to a single problem at a time.
- 2) **DATA GRID:-** It deals with the controlled sharing and management of distributed data of large amount.
- 3) **COLLABORATIVE GRID:-** It is the grid which solves collaborative problems.
- 4) **MANUSCRIPT GRID:-** This grid works well when things are presenting in large continuous blocks of text or images.
- 5) **MODULAR GRID:-** This grid works well when columns alone don't offer enough flexibility for complex problems.

■ **ADVANTAGES OF GRID COMPUTING:-**

- 1) It can solve more complex problems in a very short span of time.
- 2) It can easily combine with other organization.
- 3) It can make better use of existing hardware.

Distributed Computing:

- Distributed computing is a computing concept that, in its most general sense, refers to multiple computer systems working on a single problem. In distributed computing, a single problem is divided into many parts, and each part is solved by different computers. As long as the computers are networked, they can communicate with each other to solve the problem. If done properly, the computers perform like a single entity.
- The ultimate goal of distributed computing is to maximize performance by connecting users and IT resources in a cost-effective, transparent and reliable manner. It also ensures fault tolerance and enables resource accessibility in the event that one of the components fails.

- 
- A distributed computing architecture consists of a number of client machines with very lightweight software agents installed with one or more dedicated distributed computing management servers. The agents running on the client machines usually detect when the machine is idle and send a notification to the management server that the machine is not in use and available for a processing job. The agents then requests an application package. When the client machine receives this application package from the management server to process, it runs the application software when it has free CPU cycles and sends the result back to the management server. When the user returns and requires the resources again, the management server returns the resources was using to perform different tasks in the user's absence.

- 
- 
- Grid can be thought as a distributed system with non interactive workload that involve a large number of files.

- **Utility Computing:**

Utility computing is the process of providing computing service through an on-demand, pay-per-use billing method. Utility computing is a computing business model in which the provider owns, operates and manages the computing infrastructure and resources, and the subscribers accesses it as and when required on a rental or metered basis.

- 
- 
- Utility computing is one of the most popular IT service models, primarily because of the flexibility and economy it provides. This model is based on that used by conventional utilities such as telephone services, electricity and gas. The principle behind utility computing is simple. The consumer has access to a virtually unlimited supply of computing solutions over the Internet or a virtual private network, which can be sourced and used whenever it's required. The back-end infrastructure and computing resources management and delivery is governed by the provider.

Utility computing solutions can include virtual servers, virtual storage, virtual software, backup and most IT solutions.

Pros and Cons of Cloud computing:

Pros:

- **No cost on infrastructure:** Cloud computing is divided into three major categories as per the services: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS).

In all these categories, one thing is common that you don't need to invest in hardware or any infrastructure. In general, every organization has to spend a lot on their IT infrastructure to set up and hire a specialized team.

Servers, network devices, ISP connections, storage, and software – these are the major things on which you need to invest if we talk about general IT infrastructure.

But if you move to cloud computing services, then you don't need to invest in these. You simply go to a [cloud services provider](#) and buy a cloud service.

- **Minimum management and cost:** By selecting the cloud, you save cost in many ways:

- Zero investment in infrastructure.

- Since you don't own the infrastructure, you spend nothing on its management or staff to manage it.

- Cloud works on *pay as you go* model, so you spend only on resources that you need. Nothing more!

When you opt for the cloud, the management of its infrastructure is the sole responsibility of the cloud provider and not of the user.

- 
- 
- **Forget about administrative or management hassles:** Whenever there is a purchase or up-gradation of hardware, a lot of time is wasted looking for best vendors, inviting quotations, negotiating rates, taking approvals, generating POs and waiting for delivery and then in setting up the infrastructure.

This whole process includes lots of administrative/managerial tasks that waste a lot of time.

With cloud services, you just need to compare the best cloud service providers and their plans and buy from the one that matches your requirements. And this whole process doesn't take much time and saves you a lot of efforts. Your system maintenance tasks are also eliminated in the cloud.

- 
- 
- **Accessibility and pay per use:** Cloud resources are easily accessible from around the globe – anytime, anywhere and from any device and you have complete access to your resources.

This decides your billing also -you only pay for what you use and how much you use. It's like your phone or electricity bill. But with other IT infrastructure, one spends the complete amount in one go and it is very very rare that those resources are used optimally and thus, the investment goes waste.

- **Reliability:** Your infrastructure in the cloud increases the reliability and availability of applications and services. Cloud services run on pooled and redundant infrastructure which provides you with a higher availability of IT services.
- **Data control:** Another primary advantage of the cloud is that it centralizes all the data from multiple projects and branch offices to a single location. You gain complete control over the data without visiting individual places for checking the information.
- **Data backup & recovery:** Loss of data can significantly impact your business. You might lose critical information which can cost you a huge sum of money, waste your valuable time and adversely impact your brand image.

To prevent it, you can automatically backup all the data to the cloud on a regular basis. This helps you to recover any data in case of accidental deletion, loss because of natural calamity or if the hard drive crashes.

- **Huge cloud storage:** Most cloud services provide you a free, secure and huge storage space to store all your valuable information.

Although most cloud storage services like OneDrive offer you a good amount of free storage, if you use it all, you can always go for buying more secure storage in the cloud.

- **Automatic software updates:** Updating a system every now and then can be a frustrating task for enterprises. The IT department needs to update the system for every individual which not only wastes time but affects productivity.

But if you are using cloud-based applications, they will get automatically updated, without any involvement from the users.

Cons of cloud computing:

- **Requires good speed internet with good bandwidth:** To access your cloud services, you need to have a good internet connection always with good bandwidth to upload or download files to/from the cloud
- **Downtime:** Since the cloud requires high internet speed and good bandwidth, there is always a possibility of service outage, which can result in business downtime. Today, no business can afford revenue or business loss due to downtime or slow down from an interruption in critical business processes.
- **Limited control of infrastructure:** Since you are not the owner of the infrastructure of the cloud, hence you don't have any control or have limited access to the cloud infra.

- **Restricted or limited flexibility:** The cloud provides a huge list of services, but consuming them comes with a lot of restrictions and limited flexibility for your applications or developments. Also, platform dependency or 'vendor lock-in' can sometimes make it difficult for you to migrate from one provider to another.
- **Ongoing costs:** Although you save your cost of spending on whole infrastructure and its management, on the cloud, you need to keep paying for services as long as you use them. But in traditional methods, you only need to invest once.
- **Security:** Security of data is a big concern for everyone. Since the public cloud utilizes the internet, your data may become vulnerable.

In the case of a public cloud, it depends on the cloud provider to take care of your data. So, before opting for cloud services, it is required that you find a provider who follows maximum compliance policies for data security.

For complete security of data on the cloud, one needs to consider a somewhat costlier private cloud option or the hybrid cloud option, where generic data can be on the public cloud and business-critical data is kept on the private cloud.

- **Vendor Lock-in:** Although the cloud service providers assure you that they will allow you to switch or migrate to any other service provider whenever you want, it is a very difficult process.

You will find it complex to migrate all the cloud services from one service provider to another. During migration, you might end up facing compatibility, interoperability and support issues. To avoid these issues, many customers choose not to change the vendor.

- **Technical issues:** Even if you are a tech whiz, the technical issues can occur, and everything can't be resolved in-house. To avoid interruptions, you will need to contact your service provider for support. However, not every vendor provides 24/7 support to their clients.

A list of advantages and disadvantages of cloud computing:

Advantages of Cloud	Disadvantages of Cloud
No cost of infrastructure	Good internet connection & bandwidth required
Minimum management and cost	Downtime
No administrative or management hassles	Limited control of infrastructure
Easy accessibility	Restricted or limited flexibility
Pay per use	Ongoing costs
Reliability	Security
Data control	Vendor lock-in
Data backup and recovery	Technical Issues
Huge cloud storage	NA

■ Benefits of cloud computing

Cloud computing offers your business many benefits. It allows you to set up what is essentially a virtual office to give you the flexibility of connecting to your business anywhere, any time. With the growing number of web-enabled devices used in today's business environment (e.g. smartphones, tablets), access to your data is even easier.

There are many benefits to moving your business to the cloud:

■ **Reduced IT costs**

Moving to cloud computing may reduce the cost of managing and maintaining your IT systems. Rather than purchasing expensive systems and equipment for your business, you can reduce your costs by using the resources of your cloud computing service provider. You may be able to reduce your operating costs because:

- the cost of system upgrades, new hardware and software may be included in your contract
- you no longer need to pay wages for expert staff
- your energy consumption costs may be reduced
- there are fewer time delays.

■ Scalability

Your business can scale up or scale down your operation and storage needs quickly to suit your situation, allowing flexibility as your needs change. Rather than purchasing and installing expensive upgrades yourself, your cloud computer service provider can handle this for you. Using the cloud frees up your time so you can get on with running your business.

■ Business continuity

Protecting your data and systems is an important part of business continuity planning. Whether you experience a natural disaster, power failure or other crisis, having your data stored in the cloud ensures it is backed up and protected in a secure and safe location. Being able to access your data again quickly allows you to conduct business as usual, minimizing any downtime and loss of productivity.

- **Collaboration efficiency**

Collaboration in a cloud environment gives your business the ability to communicate and share more easily outside of the traditional methods. If you are working on a project across different locations, you could use cloud computing to give employees, contractors and third parties access to the same files. You could also choose a cloud computing model that makes it easy for you to share your records with your advisers (e.g. a quick and secure way to share accounting records with your accountant or financial adviser).

- **Flexibility of work practices**

Cloud computing allows employees to be more flexible in their work practices. For example, you have the ability to access data from home, on holiday, or via the commute to and from work (providing you have an internet connection). If you need access to your data while you are off-site, you can connect to your virtual office, quickly and easily.

- **Access to automatic updates**

Access to automatic updates for your IT requirements may be included in your service fee. Depending on your cloud computing service provider, your system will regularly be updated with the latest technology. This could include up-to-date versions of software, as well as upgrades to servers and computer processing power.

Evolution of Cloud Computing:

Cloud computing is all about renting computing services. This idea first came in the 1950s. In making cloud computing what it is today, five technologies played a vital role. These are distributed systems and its peripherals, virtualization, web 2.0, service orientation, and utility computing.

Evolution of Cloud Computing

■ **Distributed Systems:**

It is a composition of multiple independent systems but all of them are depicted as a single entity to the users. The purpose of distributed systems is to share resources and also use them effectively and efficiently. Distributed systems possess characteristics such as scalability, concurrency, continuous availability, heterogeneity, and independence in failures. But the main problem with this system was that all the systems were required to be present at the same geographical location. Thus to solve this problem, distributed computing led to three more types of computing and they were-Mainframe computing, cluster computing, and grid computing.

■ Mainframe

computing:

Mainframes which first came into existence in 1951 are highly powerful and reliable computing machines. These are responsible for handling large data such as massive input-output operations. Even today these are used for bulk processing tasks such as online transactions etc. These systems have almost no downtime with high fault tolerance. After distributed computing, these increased the processing capabilities of the system. But these were very expensive. To reduce this cost, cluster computing came as an alternative to mainframe technology.

■ Cluster

computing:

In 1980s, cluster computing came as an alternative to mainframe computing. Each machine in the cluster was connected to each other by a network with high bandwidth. These were way cheaper than those mainframe systems. These were equally capable of high computations. Also, new nodes could easily be added to the cluster if it was required. Thus, the problem of the cost was solved to some extent but the problem related to geographical restrictions still pertained. To solve this, the concept of grid computing was introduced.

■ Grid computing:

In 1990s, the concept of grid computing was introduced. It means that different systems were placed at entirely different geographical locations and these all were connected via the internet. These systems belonged to different organizations and thus the grid consisted of heterogeneous nodes. Although it solved some problems but new problems emerged as the distance between the nodes increased. The main problem which was encountered was the low availability of high bandwidth connectivity and with it other network associated issues. Thus, cloud computing is often referred to as “Successor of grid computing”.

■

■ Virtualization:

It was introduced nearly 40 years back. It refers to the process of creating a virtual layer over the hardware which allows the user to run multiple instances simultaneously on the hardware. It is a key technology used in cloud computing. It is the base on which major cloud computing services such as Amazon EC2, VMware vCloud, etc work on. Hardware virtualization is still one of the most common types of virtualization.

Web 2.0:

It is the interface through which the cloud computing services interact with the clients. It is because of Web 2.0 that we have interactive and dynamic web pages. It also increases flexibility among web pages. Popular examples of web 2.0 include Google Maps, Facebook, Twitter, etc. Needless to say, social media is possible because of this technology only. It gained major popularity in 2004.

- **Service orientation:**

It acts as a reference model for cloud computing. It supports low-cost, flexible, and evolvable applications. Two important concepts were introduced in this computing model. These were Quality of Service (QoS) which also includes the SLA (Service Level Agreement) and Software as a Service (SaaS).

- **Utility computing:**

It is a computing model that defines service provisioning techniques for services such as compute services along with other major services such as storage, infrastructure, etc which are provisioned on a pay-per-use basis.

Thus, the above technologies contributed to the making of cloud computing.

Business drivers for adopting cloud computing:

- **Business Hike:**

Analyzing your moves gives fabricated results. Thus, if you view a certain range of hike in your business, it might be one of the cloud drivers. The growth in business is one of the major obligations, that any organization could ever rate.

Therefore, based on the steps of the plan for driving the cloud services, it is prominent to boil out the business strategy by the consideration of cloud adoption.

- **- Balanced Cost Structure:**

This is one of the most recognized factors, acting as a driver for cloud adoption. The number of organizations has witnessed that employing the cloud bolsters in cutting the cost, resulting in turning down of **license for legacy systems**.

Depending on the cloud for acquiring **cloud storage services**, reduction in office space and attaining the quality, domes as the driver for cloud adoption.

■ **Improved Productivity:**

When the organizations are adopting the means of fabricated technology, it is believed to view tremendous change in the range of productivity.

Productivity is the factor, often considered as a driver of cloud adoption. If the cloud is structured at a significant rate, it could produce imitable results, in favour of an organization.

■ **- Efficiency:**

Improved Efficiency, with minimal errors, is one of the key drivers, propagating the reasons for adoption of the cloud.

When the organization adopts any newer means of technology, it always has an underlying motive to access the medium for fulfilling the business requirement, with a hike in business and optimized cloud solutions. At its core, efficiency is about removing unnecessary steps to streamline processes in order to increase productivity or deliver on customer requirements faster

- **Scalability:**

The scalable service of the cloud is one the biggest key driver, acting in the favor of organizations. The cloud-enabled services are swaddled in such a manner that one can scale the range of services as per its requirement.

One can add on more number of services with customized features if the organization feels ready to step up. Also, the organization can step down in terms of services, if it finds it as the far-reaching target.

- **NIST Model:**

NIST is part of the U.S. Department of Commerce and works to promote the economy and public welfare by providing technical leadership for measurement and standards infrastructure.

From the NIST definition of cloud computing, “Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interactive.” NIST provides the following definitions of the essential characteristics and service and deployment models for cloud computing.

Essential Cloud Computing Characteristics:

- On-demand self-service: consumers can unilaterally provision computing capabilities as needed automatically without requiring human interaction with each service provider.
- Broad network access: capabilities are available over the network and accessed through standard mechanism that promote use by heterogeneous thin or thick client platforms.
- Resources pooling: The provider's computing resources are pooled to serve multiple consumers using a multi-tenant model, with different physical and virtual resources dynamically assigned and reassigned according to consumer demand
- Rapid elasticity: capabilities can be elastically provisioned and released to scale rapidly outward and inward commensurate with demand.
- Measured service: cloud systems automatically control and optimize resource use by leveraging a metering capability at some level of abstraction appropriate to the type of service.

Service Models: The many paradigms of cloud computing can be broken down into three unique service model classifications: Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS).

- Software as a Service (SaaS)
- Platform as a Service (PaaS)
- Infrastructure as a Service (IaaS)

Deployment Models:

- Private cloud
- Community cloud
- Public cloud
- Hybrid cloud

Infrastructure as a Service | IaaS

- IaaS is also known as **Hardware as a Service (HaaS)**. It is one of the layers of the cloud computing platform. It allows customers to outsource their IT infrastructures such as servers, networking, processing, storage, virtual machines, and other resources. Customers access these resources on the Internet using a pay-as-per use model.
- In traditional hosting services, IT infrastructure was rented out for a specific period of time, with pre-determined hardware configuration. The client paid for the configuration and time, regardless of the actual use. With the help of the IaaS cloud computing platform layer, clients can dynamically scale the configuration to meet changing requirements and are billed only for the services actually used.

A cloud computing service provider, such as Azure, manages the infrastructure, while you purchase, install, configure and manage your own software—operating systems, middleware and applications.

- 
- 
- IaaS provider provides the following services -
 - **Compute:** Computing as a Service includes virtual central processing units and virtual main memory for the Vms that is provisioned to the end- users.
 - **Storage:** IaaS provider provides back-end storage for storing files.
 - **Network:** Network as a Service (NaaS) provides networking components such as routers, switches, and bridges for the Vms.
 - **Load balancers:** It provides load balancing capability at the infrastructure layer.

Advantages of IaaS cloud computing layer

There are the following advantages of IaaS computing layer -

- **1. Shared infrastructure**

IaaS allows multiple users to share the same physical infrastructure.

- **2. Web access to the resources**

IaaS allows IT users to access resources over the internet.

- **3. Pay-as-per-use model**

IaaS providers provide services based on the pay-as-per-use basis. The users are required to pay for what they have used.

- **4. Focus on the core business**

IaaS providers focus on the organization's core business rather than on IT infrastructure.

- **5. On-demand scalability**

On-demand scalability is one of the biggest advantages of IaaS. Using IaaS, users do not worry about to upgrade software and troubleshoot the issues related to hardware components.

Disadvantages of IaaS:

- **1. Security**

Security is one of the biggest issues in IaaS. Most of the IaaS providers are not able to provide 100% security.

- **2. Maintenance & Upgrade**

Although IaaS service providers maintain the software, but they do not upgrade the software for some organizations.

- **3. Interoperability issues**

It is difficult to migrate VM from one IaaS provider to the other, so the customers might face problem related to vendor lock-in.

Top IaaS Providers who are providing IaaS cloud computing platform

IaaS Providers

Pizza as a Service

■ IaaS (Infra as a Service)

IaaS provides the infrastructure such as virtual machines and other resources like virtual-machine disk image library, block and file-based storage, firewalls, load balancers, IP addresses, virtual local area networks etc. Infrastructure as service or IaaS is the basic layer in cloud computing model.

Common examples: DigitalOcean, Linode, Rackspace, Amazon Web Services (AWS), Cisco Metapod, Microsoft Azure, Google Compute Engine (GCE) are some popular examples of IaaS.

■ PaaS (Platform as a Service)

PaaS or platform as a service model provides you computing platforms which typically includes an operating system, programming language execution environment, database, web server. technically It is a layer on top of IaaS as the second thing you demand after Infrastructure is a platform.

Common examples: AWS Elastic Beanstalk, Windows Azure, Heroku, Force.com, Google App Engine, Apache Stratos.

- **SaaS (Software as a Service)**

In a SaaS, you are provided access to application services installed at a server. You don't have to worry about installation, maintenance or coding of that software. You can access and operate the software with just your browser. You don't have to download or install any kind of setup or OS, the software is just available for you to access and operate. The software maintenance or setup or help will be provided by SaaS provider company and you will only have to pay for your usage.

Common examples: Google Apps, Microsoft office365, Google docs, Gmail, WHMCS billing software

■ Platform as a Service | PaaS

Platform as a Service (PaaS) provides a runtime environment. It allows programmers to easily create, test, run, and deploy web applications. You can purchase these applications from a cloud service provider on a pay-as-per use basis and access them using the Internet connection. In PaaS, back end scalability is managed by the cloud service provider, so end- users do not need to worry about managing the infrastructure.

PaaS includes infrastructure (servers, storage, and networking) and platform (middleware, development tools, database management systems, business intelligence, and more) to support the web application life cycle.

Example: Google App Engine, Force.com, Joyent, Azure.

- The de

- PaaS providers provide the Programming languages, Application frameworks, Databases, and Other tools:

- **Programming languages**

PaaS providers provide various programming languages for the developers to develop the applications. Some popular programming languages provided by PaaS providers are Java, PHP, Ruby, Perl, and Go.

- **2. Application frameworks**

PaaS providers provide application frameworks to easily understand the application development. Some popular application frameworks provided by PaaS providers are Node.js, Drupal, Joomla, WordPress, Spring, Play, Rack, and Zend.

- **3. Databases**

PaaS providers provide various databases such as ClearDB, PostgreSQL, MongoDB, and Redis to communicate with the applications.

- **4. Other tools**

PaaS providers provide various other tools that are required to develop, test, and deploy the applications.

Advantages of PaaS

There are the following advantages of PaaS -

- **1) Simplified Development**

PaaS allows developers to focus on development and innovation without worrying about infrastructure management.

- **2) Lower risk**

No need for up-front investment in hardware and software. Developers only need a PC and an internet connection to start building applications.

- **3) Prebuilt business functionality**

Some PaaS vendors also provide already defined business functionality so that users can avoid building everything from very scratch and hence can directly start the projects only.

- **4) Instant community**

PaaS vendors frequently provide online communities where the developer can get the ideas to share experiences and seek advice from others.

- **5) Scalability**

Applications deployed can scale from one to thousands of users without any changes to the applications.

Disadvantages of PaaS:

- **Vendor lock-in**

One has to write the applications according to the platform provided by the PaaS vendor, so the migration of an application to another PaaS vendor would be a problem.

For example, an application written in Python against API of Google, and using App Engine of Google is likely to work only in that environment.

- **2) Data Privacy**

Corporate data, whether it can be critical or not, will be private, so if it is not located within the walls of the company, there can be a risk in terms of privacy of data.

- **3) Integration with the rest of the systems applications**

It may happen that some applications are local, and some are in the cloud. So there will be chances of increased complexity when we want to use data which in the cloud with the local data.

- **What is Software-as-a-Service (SaaS)?**

Software-as-a-Service, or SaaS for short, is a cloud-based method of providing software to users. SaaS users subscribe to an application rather than purchasing it once and installing it. Users can log into and use a SaaS application from any compatible device over the Internet. The actual application runs in cloud servers that may be far removed from a user's location.

Non-SaaS Application

Application logic runs
on user's computer

SaaS Application

Application logic runs
in the cloud

- A SaaS application may be accessed through a browser or through an app. Online email applications that users access through a browser, such as Gmail and Office 365, are common examples of SaaS applications.
- The difference between SaaS and a software installation on a user's computer is somewhat like the difference between streaming a TV show online and buying all the seasons of the TV show on DVD.
- Someone who buys a TV show on DVD only needs to pay for it once; however, they will need to store and maintain the DVDs, and if they change their hardware – for instance, if they replace their DVD player with a Blu-ray player – then they will need to purchase the physical media again. Streaming the show instead means a third party handles all the storage and upgrades, and all a user needs to do is press play. However, streaming is dependent on an Internet connection, and users typically need to pay a recurring monthly fee to maintain their access.

Users can access SaaS applications on any device

What does 'as a service' mean?

- Consider the difference between valet parking and renting a parking spot. Valet parking is a service, while a parking spot is a product, even though both provide the same benefit to the customer: a place to leave their car.
- Traditionally, software vendors sold their software to users as a product. However, in the SaaS model they actively provide and maintain the software for their users, via the cloud. They host and maintain the databases and code necessary for the application to run, and they run the application on their servers. Thus, SaaS is more like a service than a product.

■ What is the cloud?

- "The cloud" refers to remote web servers in various data centers that host databases and run application code. Cloud providers deliver their services to customers or end users via the Internet.

What are the advantages and disadvantages of using SaaS?

- The SaaS model has a number of pros and cons, although for modern businesses and users the pros of SaaS often outweigh the cons. Here are some of the advantages and disadvantages of using SaaS applications:

Advantage:

- **Access from anywhere, on any device.** Typically, users can log into SaaS applications from any device and any location. This offers a great deal of flexibility – businesses can allow employees to operate all over the world, and users can access their files no matter they are. In addition, most users use multiple devices and replace them often; users don't need to reinstall SaaS applications or purchase new licenses each time they switch to a new device.
- **No need for updates or installations.** The SaaS provider updates and patches the application on an ongoing basis.
- **Scalability.** The SaaS provider handles scaling up the application, such as adding more database space or more compute power as usage increases.
- **Cost savings.** SaaS cuts down on internal IT costs and overhead. The SaaS provider maintains the servers and infrastructure that support the application, and the only cost to a business is the subscription cost of the application.

■ **Disadvantage:**

- **The need for stronger access control.** The increased accessibility of SaaS applications also means that verifying user identity and controlling access levels becomes very important. With SaaS, organizational assets are no longer kept within an internal network, separate from the outside world. Instead, user access is based on user identity: if someone has the right login credentials, they are granted access. Strong identity verification thus becomes crucial.
- **Vendor lock-in.** A business may become overly reliant on the SaaS application provider. It's time-consuming and expensive to move to a new application if an organization's entire database is stored within the old application.
- **Disadvantage (for enterprises): Security and compliance.** With SaaS applications, the responsibility for protecting those applications and their data moves from internal IT teams to the external SaaS providers. For small to medium-sized businesses, this is less of a disadvantage, as large cloud providers typically have more resources for putting strong security in place. But this can be a challenge if a large business faces tight security or regulatory standards. In some cases businesses will be unable to assess their applications' security themselves, for instance by performing penetration testing. Essentially, they have to take the external SaaS provider's word that the application is secure.

- **Cloud Computing Stack:**

- Cloud computing is a broad term that describes a wide range of services. We can categorise cloud services into one of three offerings: software-as-a-service (SaaS), platform-as-a-service (PaaS) and infrastructure-as-a-service (IaaS). They are called 'as a service' because businesses purchase them as service products from third parties. Together, they are the **cloud computing stack**.
- SaaS are used by end users such as employees in a business, programmers use PaaS for developing applications, and IaaS are used by network architects to design a firm's IT systems

- 
- 
- Cloud computing has commonly been referred to as a “stack” because it typically encompasses many different types of services which have been built on top of each other under a “cloud”. Cloud computing has been defined by the NIST (National Institute of Standards and Technology) as a model that enables on-demand access to a shared resource pool consisting of servers, networks, applications, services and storage which can be rapidly deployed with minimal management efforts. There are three different types of cloud computing services namely Platform as a Service or PaaS, Software as a Service or SaaS and Infrastructure as a Service or IaaS.
